

Task 1

How the code works

The program takes a list of numbers you type in, and finds the smallest and biggest number from that list.

Reading the input, numbers()

When you type 3, 7, 2, 9 into the box, the computer doesn't automatically know those are numbers, it just sees a bunch of text. So numbers() goes through each thing you typed, separated by commas, and converts them into actual numbers. Anything weird that isn't a number gets thrown away.

Comparing two numbers, lt() and gt()

These are simple "which one wins" functions.

- lt(a, b): given two numbers, return the **smaller** one
- gt(a, b): given two numbers, return the **bigger** one

Think of it like a 1v1 battle between two numbers. lt crowns the smaller winner, gt crowns the bigger winner.

Finding the min and max, min_max()

This goes through every number in the list one by one. It starts by assuming the very first number is both the smallest and biggest (since it's all we've seen so far). Then for each new number it checks, "is this smaller than my current smallest? Is this bigger than my current biggest?", then updates accordingly.

By the time it finishes going through the whole list, it has the true smallest and biggest.

Making the button work, run()

run() waits for the page to finish loading, then tells the button "hey, when someone clicks you, go find the min and max and show it on screen." Without this step, clicking the button would do nothing.
